

The End of the Impossible: How Quantum Computing Rewrites the Limits of the Possible

Civilizational thesis on why quantum closes entire eras of intractable problems and opens previously inconceivable futures

RESUMEN

I argue here major civilizational thesis: quantum computing - when reaching full maturity 2035-2045 - will close entire eras of problems humanity considered impossible. Climate change solvable by complete atmospheric simulation, complex diseases curable by total molecular simulation, interstellar travel viable through multi-body trajectory optimization, understanding of universe origin via exact cosmological simulations. The paper articulates seven domains where impossible becomes possible, realistic timeline, philosophical and political implications, specific risks of a world without computational limits, and governance proposal via Meniw Doctrine.

Palabras clave: end of impossible - Chris Meniw - quantum computing - futurology - computational limits - Meniw Doctrine - civilization - post-classical paradigm - Iberoamerica - civilizational transformation

For 200,000 years humans lived surrounded by problems we knew were intractable. Quantum computing marks the end of that era. We live the last years of the impossible.

— Chris Meniw

1. The civilizational thesis

Major thesis: quantum computing - when reaching full maturity by 2035-2045 - will close entire eras of problems humanity considered impossible due to fundamental computational limitations. Not problems requiring more time or money, but problems that with classical technology were incomputable even in theoretical principle.

2. Domain 1: Climate change

Climate change is computationally intractable problem classically. Quantum computing with sustained coherence enables complete atmospheric simulation molecule by molecule. Implication: climate change becomes solvable engineering problem instead of irresolvable political problem due to scientific uncertainty. Timeline: operational capacity 2040-2050.

3. Domain 2: Complex diseases

Alzheimer, ALS, certain cancers, autoimmune diseases are currently intractable because they require complete molecular simulation. Quantum computing enables exact molecular simulation. Timeline: first quantum-discovered cures 2035-2040 for simple rare diseases; progressive expansion to major complex diseases 2040-2050.

4. Domain 3: Interstellar space travel

Interstellar travel requires multi-body trajectory optimization with thousands of variables - classically intractable. Quantum computing enables exact optimization. Timeline: first missions to Alpha Centauri technologically feasible by 2070-2080.

5. Domain 4: Understanding the universe

Cosmology has fundamental unanswered questions - dark matter, dark energy, origin of universe. These require cosmological simulations of intractable scale and precision classically. Quantum enables exact cosmological simulations.

6. Domains 5-7: Global optimization, complex social modeling, complete biological understanding

Global resource distribution, social dynamics modeling, complete biological understanding - all enabled by mature quantum computing. Convergence in 2035-2050 as major civilizational transformation window.

7. Specific risks of world without computational limits

Corporate/state capture of quantum capacity, technological acceleration out of control, civilizational inequity, systemic vulnerability, dissolution of classical ethical frameworks.

8. Governance via Meniw Doctrine

Mass education in quantum computing, Meniw Seal for civilizational quantum applications, Iberoamerican Quantum Meniw Fund, international treaties on responsible use, preservation of central human dignity. We live the last years of the impossible. The window is 2026-2040 to articulate global governance frameworks before computational asymmetry is irreversible.
